Main Website

This the website I created with the basic shopping cart, where a user can checkout. The files include index.jp, subpage.jp, ShoppingCart.jsp and final.jsp.

WebApplication1 is where the API was created. Within this, there is a form that calls the ExpressCheckouts doPost function. This basically calls the doGet function, within which the return and cancel urls are generated from the server. This also calls the callShortcutExpressCheckout function where SetExpressCheckout is called using the httpcall function. if the ACK is success, it returns a token which directs it to the paypal website. Once the user logs in and verifies the details, another id and token is appended to the return URL. GetExpressCheckoutDetails is called then, and if successful returns the details of the user. Then the DoExpressCheckoutPayment form is then executed.
